

Shortest measurement distance for optical power meters

Overview

In conclusion, an optical power meter is designed to measure the power of optical signals at specific wavelengths, primarily 850 nm for short-distance applications and 1300-1310 nm for medium-distance applications. The term usually refers to a device used for measuring the average power in fiber optic systems. Other general purpose light power measuring devices are usually called radiometers, photometers, laser power. While optical power meters are the primary power measurement instrument, optical loss test sets (OLTSS) and optical time domain reflectometers (OTDRs) also measure power in testing loss. An optical power meter (OPM) doesn't have a single "wavelength" of its own; instead. To combat this issue, researchers in the group of Professor Xavier Attenu at Amsterdam UMC in the Netherlands have developed an efficient, low-cost method for characterizing the length of optical fibers; their results are available in Optics Letters. Pulsed time-of-flight and phase shift measurement.

A typical OPM is linear from about 0 dBm (1 milli Watt) to about -50 dBm (10 nano Watt), although the display range may be larger. Above 0 dBm is considered "high power", and specially adapted units may measure up to nearly + 30 dBm (1 Watt). Below -50 dBm is "low power", and specially adapted units may measure as low as -110 dBm. Irrespective of power meter specifications, testing below about -50 dBm tends to be sensitive to stray ambient light leaking into fibers or connectors. So when testing at "l
